Abstract

The reaction $\gamma\gamma \rightarrow J/\Psi J/\Psi$ is discussed assuming dominance of the QCD BFKL pomeron exchange. We give prediction for the cross-section of this process for LEP2 and TESLA energies. We solve the BFKL equation in the non-forward configuration taking into account dominant non-leading effects which come from the requirement that the virtuality of the exchanged gluons along the gluon ladder is controlled by their transverse momentum squared. We compare our results with those corresponding to the simple two gluon exchange mechanism and with the BFKL pomeron exchange in the leading logarithmic approximation. The BFKL effects are found to generate a steeper t -dependence than the two gluon exchange. The cross-section is found to increase with increasing CM energy W as $(W^2)^{2\lambda}$. The parameter λ is slowly varying with W and takes the values $\lambda \sim 0.23 - 0.28$. The magnitude of the total cross-section for the process $\gamma\gamma \rightarrow J/\Psi J/\Psi$ is found to increase from 4 to 26 pb within the energy range accessible at LEP2. The magnitude of the total cross-section for the process $e^+e^- \rightarrow e^+e^- J/\Psi J/\Psi$ with antitagged e^+ and e^- is estimated to be around 0.1 pb at LEP2.

The high energy limit of elementary processes in perturbative QCD is at present theoretically fairly well understood [1, 2]. The leading behaviour is controlled by the pomeron singularity which corresponds to the sum of ladder diagrams with reggeized gluons along the chain. This sum is described by the Balitzkij, Fadin, Kuraev, Lipatov (BFKL) equation [3]. Possible phenomenological tests of the perturbative QCD pomeron exchange are however difficult. First of all they have to be limited to (semi-) hard processes in which the presence of the hard scale(s) can justify the use of perturbative QCD. Moreover in order to minimize the possible role of the non-perturbative contributions it is in principle necessary to focus on the processes which directly probe the high energy limit of partonic amplitudes alone. Finally in order to extract the genuine BFKL effects which go beyond the conventional QCD evolution with ordered transverse momenta from one scale to another it is also useful to consider the processes with small (or equal to zero) "evolution length" i.e. those where the magnitudes of the two hard scales are comparable. The two classical processes which can probe the QCD pomeron by fulfilling these criteria are deep inelastic events accompanied by an energetic (forward) jet [4, 5]) and the production of large p_T jets separated by the rapidity gap [6]. The former process probes the QCD pomeron in the forward direction while the latter reflects the elastic scattering of partons via the QCD pomeron exchange with non-zero (and large) momentum transfer. Another possible probe of the QCD pomeron at (large) momentum transfers can be provided by the diffractive vector meson photo-production accompanied by proton dissociation in order to avoid nucleon form-factor effects [7, 8], while the complementary measurement to deep inelastic scattering + jet events may also be the total $\gamma^*\gamma^*$ cross section of virtual photons having comparable virtuality [9].

In this paper we wish to analyze the double diffractive production of J/Ψ in $\gamma\gamma$ collisions i.e. the process $\gamma\gamma \rightarrow J/\Psi J/\Psi$ assuming exchange of the QCD pomeron (see Fig. 1). It should be noted that both sides of the diagram shown in Fig. 1 are characterized by the same (hard) scale provided in this case by the relatively large charmed quark mass. In this sense this process is complementary to the classical measurements listed above. One of its merits is the fact that in this process we can in principle "scan" the perturbative QCD pomeron for arbitrary values of the momentum transfer. In fact the diffractive reaction $\gamma\gamma \rightarrow J/\Psi J/\Psi$ is unique in this respect since the measurements listed above do only probe the QCD pomeron either in forward direction or for large momentum transfers. In the diffractive double J/Ψ production in $\gamma\gamma$ collisions the hard scale is provided by the charmed quark mass and the theoretical description in

Figure 1: The QCD pomeron exchange mechanism of the process $\gamma\gamma \rightarrow J/\Psi J/\Psi$.

terms of the perturbative QCD pomeron exchange is applicable for arbitrary momentum transfers. This process has also the advantage that its cross-section can be almost entirely calculated perturbatively. The only non-perturbative element is a parameter determined by the J/Ψ light cone wave function which can however be obtained from the measurement of the leptonic width $\Gamma_{J/\Psi \rightarrow l+l-}$ of the J/Ψ .

The imaginary part $ImA(W^2, t = -Q^2)$ of the amplitude for the process $\gamma\gamma \rightarrow J/\Psi J/\Psi$ which corresponds to the diagram in Fig. 1 illustrating the QCD pomeron exchange can be written in the following form:

$$ImA(W^2, t = -Q^2) = \int \frac{d^2\mathbf{k}}{\pi} \frac{\Phi_0(k^2, Q^2)\Phi(x, \mathbf{k}, \mathbf{Q})}{[(\mathbf{k} + \mathbf{Q}/2)^2 + s_0][(\mathbf{k} - \mathbf{Q}/2)^2 + s_0]} \quad (1)$$

In this equation $x = m_{J/\Psi}^2/W^2$ where W denotes the total CM energy of the $\gamma\gamma$ system, $m_{J/\Psi}$ is the mass of the J/Ψ meson, $\mathbf{Q}/2 \pm \mathbf{k}$ denote the transverse momenta of the exchanged gluons and $\mathbf{Q}$ is the transverse part of the momentum transfer. In the propagators corresponding to the exchanged gluons we include the parameter s_0 which can be viewed upon as the effective representation of the inverse of the colour confinement radius squared. Sensitivity of the cross-section to its magnitude can serve as an estimate of the sensitivity of the results to the contribution coming from the infrared region. It should be noted that formula (1) gives finite result in the limit $s_0 = 0$.

Figure 2: The diagrams describing the coupling of two gluons to the $\gamma \rightarrow J/\Psi$ transition vertex.

The impact factor $\Phi_0(k^2, Q^2)$ describes the $\gamma J/\Psi$ transition induced by two gluons and the diagrams defining this factor are illustrated in Fig. 2. In the nonrelativistic approximation they give the following formula for $\Phi_0(k^2, Q^2)$ [7, 11]:

$$\Phi_0(k^2, Q^2) = \frac{C}{2} \sqrt{\alpha_{em}} \alpha_s(\mu^2) \left[\frac{1}{\bar{q}^2} - \frac{1}{m_{J/\Psi}^2/4 + k^2} \right] \quad (2)$$

where

$$C = q_c \frac{8}{3} \pi m_{J/\Psi} f_{J/\Psi} \quad (3)$$

with $q_c = 2/3$ denoting the charge of a charm quark and

$$\bar{q}^2 = \frac{m_{J/\Psi}^2 + Q^2}{4} \quad (4)$$

The parameter $f_{J/\Psi}$ which characterizes the light cone wave function of the J/Ψ can be related in the leading order to the leptonic width $\Gamma_{J/\Psi \rightarrow l+l^-}$ of the J/Ψ

$$f_{J/\Psi} = \sqrt{\frac{3m_{J/\Psi} \Gamma_{J/\Psi \rightarrow l+l^-}}{2\pi \alpha_{em}^2}} \quad (5)$$

In our calculations we will set $f_{J/\Psi} = 0.38$ GeV. Equation (5) can in principle acquire higher order corrections which would affect the normalization factor C . It has

however been argued in ref. [12] that those corrections should be small provided that the light cone wave function is consistently used. The apparently large corrections are only present in the non-relativistic potential models where they correspond to the effect of "undressing" the constituent quarks [12] .

The function $\Phi(x, \mathbf{k}, \mathbf{Q})$ satisfies the BFKL equation which in the leading $\ln(1/x)$ approximation has the following form:

$$\begin{aligned} \Phi(x, \mathbf{k}, \mathbf{Q}) = & \Phi_0(k^2, Q^2) + \frac{3\alpha_s(\mu^2)}{2\pi^2} \int_x^1 \frac{dx'}{x'} \int \frac{d^2\mathbf{k}'}{(\mathbf{k}' - \mathbf{k})^2 + s_0} \times \\ & \left\{ \left[\frac{\mathbf{k}_1^2}{\mathbf{k}_1'^2 + s_0} + \frac{\mathbf{k}_2^2}{\mathbf{k}_2'^2 + s_0} - Q^2 \frac{(\mathbf{k}' - \mathbf{k})^2 + s_0}{(\mathbf{k}_1'^2 + s_0)(\mathbf{k}_2'^2 + s_0)} \right] \Phi(x', \mathbf{k}', \mathbf{Q}) - \right. \\ & \left. \left[\frac{\mathbf{k}_1^2}{\mathbf{k}_1'^2 + (\mathbf{k}' - \mathbf{k})^2 + 2s_0} + \frac{\mathbf{k}_2^2}{\mathbf{k}_2'^2 + (\mathbf{k}' - \mathbf{k})^2 + 2s_0} \right] \Phi(x', \mathbf{k}, \mathbf{Q}) \right\} \end{aligned} \quad (6)$$

where

$$\mathbf{k}_{1,2} = \frac{\mathbf{Q}}{2} \pm \mathbf{k}$$

and

$$\mathbf{k}'_{1,2} = \frac{\mathbf{Q}}{2} \pm \mathbf{k}' \quad (7)$$

denote the transverse momenta of the gluons. The scale of the QCD coupling α_s which appears in equations (2) and (6) will be set $\mu^2 = k^2 + Q^2/4 + m_c^2$ where m_c denotes the mass of the charmed quark. The differential cross-section is related in the following way to the amplitude A:

$$\frac{d\sigma}{dt} = \frac{1}{16\pi} |A(W^2, t)|^2 \quad (8)$$

The BFKL equation (6) sums ladder diagrams with (reggeized) gluon exchange along the ladder. Its kernel contains therefore the virtual corrections responsible for gluon reggeization besides the real gluon emission contribution. The former are given by that part of the integral in the right hand side of the equation (6) whose integrand is proportional to $\Phi(x', \mathbf{k}, \mathbf{Q})$ while the latter corresponds to the remaining part of the integral. If in eq. (1) one approximates the function $\Phi(x, \mathbf{k}, \mathbf{Q})$ by the impact factor $\Phi_0(k^2, Q^2)$ then one gets the two (elementary) gluon exchange contribution to the process $\gamma\gamma \rightarrow J/\Psi J/\Psi$ [11]. The two gluon exchange mechanism gives the cross-section which is independent of energy. A possible increase of the cross-section with energy is described by the BFKL effects generated by the solution of equation (6). These effects can also significantly affect the t dependence of the cross-section and so the process $\gamma\gamma \rightarrow J/\Psi J/\Psi$ might be a useful tool for probing the t -dependence which follows from the BFKL equation. Let us recall that in the diffractive photo-production of J/Ψ on a

proton a possible nontrivial t -dependence generated by the BFKL equation cannot be detected due to (non-perturbative) coupling of the two gluon system to a proton [10]. In order to avoid this effect one may consider the diffractive vector meson photoproduction on a proton accompanied by proton dissociation [7, 8]. In this case however the momentum transfer has to be large.

It is known that the BFKL equation can acquire significant non-leading contributions [13, 14, 15]. Although the structure of those corrections is fairly complicated their dominant part is rather simple and follows from restricting the integration region in the real emission term in equation (6). For $Q = 0$ the relevant limitation is [16, 17, 18]

$$k'^2 \leq k^2 \frac{x'}{x} \quad (9)$$

It follows from the requirement that the virtuality of the gluons exchanged along the chain is dominated by the transverse momentum squared. The constraint (9) can be shown to exhaust about 70% of the next-to-leading corrections to the QCD pomeron intercept [13, 18]. Generalization of the constraint (9) to the case of a non-forward configuration with $Q^2 \geq 0$ takes the following form:

$$k'^2 \leq (k^2 + Q^2/4) \frac{x'}{x} \quad (10)$$

Besides the BFKL equation (6) in the leading logarithmic approximation we shall therefore also consider the equation which will embody the constraint (10) in order to estimate possible effect of the non-leading contributions.

The corresponding equation which contains constraint (10) in the real emission term reads:

$$\begin{aligned} \Phi(x, \mathbf{k}, \mathbf{Q}) = & \Phi_0(k^2, Q^2) + \frac{3\alpha_s(\mu^2)}{2\pi^2} \int_x^1 \frac{dx'}{x'} \int \frac{d^2\mathbf{k}'}{(\mathbf{k}' - \mathbf{k})^2 + s_0} \times \\ & \left\{ \left[\frac{\mathbf{k}_1^2}{\mathbf{k}_1'^2 + s_0} + \frac{\mathbf{k}_2^2}{\mathbf{k}_2'^2 + s_0} - Q^2 \frac{(\mathbf{k}' - \mathbf{k})^2 + s_0}{(\mathbf{k}_1'^2 + s_0)(\mathbf{k}_2'^2 + s_0)} \right] \times \right. \\ & \Phi(x', \mathbf{k}', \mathbf{Q}) \Theta \left((k^2 + Q^2/4)x'/x - k'^2 \right) - \\ & \left. \left[\frac{\mathbf{k}_1^2}{\mathbf{k}_1'^2 + (\mathbf{k}' - \mathbf{k})^2 + 2s_0} + \frac{\mathbf{k}_2^2}{\mathbf{k}_2'^2 + (\mathbf{k}' - \mathbf{k})^2 + 2s_0} \right] \Phi(x', \mathbf{k}, \mathbf{Q}) \right\} \quad (11) \end{aligned}$$

We solved equations (6) and (11) numerically setting $m_c = m_{J/\Psi}/2$, $\Lambda_{QCD} = 0.23$ GeV and using the one loop approximation for the QCD coupling α_s with the

number of flavours $N_f = 4$. Brief summary of the numerical method and of the adopted approximations in solving equations (6,11) will be given below. Let us recall that we used a running coupling with the scale $\mu^2 = k^2 + Q^2/4 + m_c^2$. The parameter s_0 was varied within the range $0.04 \text{ GeV}^2 < s_0 < 0.16 \text{ GeV}^2$. It should be noted that the solutions of equations (6, 11) and the amplitude (1) are finite in the limit $s_0 = 0$. This follows from the fact that both impact factors $\Phi_0(k^2, Q^2)$ and $\Phi(x, \mathbf{k}, \mathbf{Q})$ vanish for $\mathbf{k} = \pm \mathbf{Q}/2$ (see equations (2, 6, 11)). The results with finite s_0 are however more realistic.

For fixed (i.e. non-running) coupling and for $s_0 = 0$ equations (6,11) could in principle be solved analytically taking advantage of the conformal invariance of their kernels. The numerical method which we adopted is however more flexible and allows to analyze equations (6,11) in the more realistic case of running α_s and non-zero s_0 .

In order to solve equations (6,11) we at first expand the function $\Phi(x, \mathbf{k}, \mathbf{Q})$ in the (truncated) Fourier series

$$\Phi(x, \mathbf{k}, \mathbf{Q}) = \sum_0^N \tilde{\Phi}_m(x, k^2, Q^2) \cos(2m\phi) \quad (12)$$

where ϕ denotes the azimuthal angle between the (two-dimensional) vectors $\mathbf{k}$ and $\mathbf{Q}$ and then we discretize the corresponding system of integral equations for the functions $\tilde{\Phi}_m(x, k^2, Q^2)$ by the Tchebyshev interpolation method. We found that the BFKL equation (6) can be to a very good accuracy approximated by retaining only the term corresponding to $m = 0$ that corresponds to neglecting possible dependence of the function $\Phi(x, \mathbf{k}, \mathbf{Q})$ upon the azimuthal angle ϕ . After retaining only the term $\tilde{\Phi}_0(x, k^2, Q^2)$ one gets the following equation for this function:

$$\begin{aligned} \tilde{\Phi}_0(x, k^2, Q^2) = & \Phi_0(k^2, Q^2) + \\ & \frac{3\alpha_s(\mu^2)}{\pi} \int_x^1 \frac{dx'}{x'} \left[\int_0^\infty dk'^2 R(k^2, k'^2, Q^2) \tilde{\Phi}_0(x', k'^2, Q^2) - \right. \\ & \left. V(k^2, Q^2) \tilde{\Phi}_0(x', k^2, Q^2) \right] \end{aligned} \quad (13)$$

where

$$R(k^2, k'^2, Q^2) = \frac{1}{\sqrt{(Q^2/4 + k'^2 + s_0)^2 - Q^2 k'^2}} \left\{ \frac{1}{\sqrt{(k^2 + k'^2 + s_0)^2 - 4k^2 k'^2}} \right.$$

Figure 3: Energy dependence of the cross-section for the process $\gamma\gamma \rightarrow J/\Psi J/\Psi$. The two lower curves correspond to the calculations based on equation (16) which contains the non-leading effects coming from the constraint (10). The continuous line corresponds to $s_0 = 0.04 \text{ GeV}^2$ and the dashed line to $s_0 = 0.16 \text{ GeV}^2$. The two upper curves correspond to equation (6) i.e. to the BFKL equation in the leading logarithmic approximation. The dashed-dotted line corresponds to $s_0 = 0.04 \text{ GeV}^2$ and short dashed line to $s_0 = 0.16 \text{ GeV}^2$.

$$\left[(k^2 + Q^2/4) - \frac{Q^2 k^2}{\sqrt{(Q^2/4 + k'^2 + s_0)^2 - Q^2 k'^2} + Q^2/4 + k'^2 + s_0} \right] - \frac{Q^2}{(Q^2/4 + k'^2 + s_0)} \Bigg\} \quad (14)$$

and

$$V(k^2, Q^2) = \int_0^\infty dk'^2 \frac{1}{\sqrt{(Q^2/4 + k'^2 + s_0)^2 - Q^2 k'^2}} \left\{ \frac{1}{\sqrt{(k^2 + k'^2 + s_0)^2 - 4k^2 k'^2}} \right. \\ \left. \left[(k^2 + Q^2/4) - \frac{Q^2 k^2}{\sqrt{(Q^2/4 + k'^2 + s_0)^2 - Q^2 k'^2} + Q^2/4 + k'^2 + s_0} \right] \right\} + \\ \int_0^{2\pi} \frac{d\phi}{2\pi} \int_0^1 d\lambda \frac{k^2 + Q^2/4 + kQ\cos(\phi)}{[k^2 + Q^2/4 + kQ\cos(\phi) + (1 + \lambda)^2 s_0]} \quad (15)$$

We assume that similar approximation can be adopted in the solution of eq. (11). Equation (11) then takes a similar form to equation (13) with additional constraint $\Theta[(k^2 + Q^2/4)x'/x - k'^2]$ imposed on the real emission terms i.e. on those terms in eq. (13) in which the corresponding integrands contain the factors $\tilde{\Phi}_0(x', k'^2, Q^2)$. The corresponding equation reads:

$$\tilde{\Phi}_0(x, k^2, Q^2) = \Phi_0(k^2, Q^2) + \\ \frac{3\alpha_s(\mu^2)}{\pi} \int_x^1 \frac{dx'}{x'} \left[\int_0^\infty dk'^2 R(k^2, k'^2, Q^2) \tilde{\Phi}_0(x', k'^2, Q^2) \Theta((k^2 + Q^2/4)x'/x - k'^2) - \right. \\ \left. V(k^2, Q^2) \tilde{\Phi}_0(x', k^2, Q^2) \right] \quad (16)$$

We based our calculations on the solutions of equations (13, 16). In Fig. 3 we show the cross-section for the process $\gamma\gamma \rightarrow J/\Psi J/\Psi$ plotted as function of the total CM energy W . We show results based on the BFKL equation in the leading logarithmic approximation as well as those which include the dominant non-leading effects. The calculations were performed for the two values of the parameter s_0 i.e. $s_0 = 0.04 \text{ GeV}^2$ and $s_0 = 0.16 \text{ GeV}^2$. We have also estimated the total cross-section for the process $e^+e^- \rightarrow e^+e^- J/\Psi J/\Psi$ with antitagged e^+ and e^- for the LEP2 energies assuming the same cuts as in ref. [19]. We get $\sigma_{e^+e^- \rightarrow e^+e^- J/\Psi J/\Psi}(\sqrt{s} = 175 \text{ GeV}) = 0.12 \text{ pb}$ and $\sigma_{e^+e^- \rightarrow e^+e^- J/\Psi J/\Psi}(\sqrt{s} = 175) = 0.09 \text{ pb}$ for $s_0 = 0.04 \text{ GeV}^2$ and $s_0 = 0.16 \text{ GeV}^2$ respectively.

In Fig.4 we show the t -dependence of the cross-section calculated for $s_0 = 0.10 \text{ GeV}^2$. We show in this Figure results for two values of the CM energy W ($W = 50 \text{ GeV}$ and

$W = 125$ GeV) obtained from the solution of the BFKL equation with the non-leading effects taken into account (see eq. (16)) and confront them with the Born term which corresponds to the two (elementary) gluon exchange. The latter is of course independent of the energy W . The values of the energy W were chosen to be in the region which may be accessible at LEP2. The following points should be emphasized:

1. We see from Fig. 3 that the effect of the non-leading contributions is very important and that they significantly reduce magnitude of the cross-section and slow down its increase with increasing CM energy W .
2. The magnitude of the cross-section decreases with increasing magnitude of the parameter s_0 which controls the contribution coming from the infrared region. This effect is however much weaker than that generated by the constraint (10) which gives the dominant non-leading contribution. The energy dependence of the cross-section is practically unaffected by the parameter s_0 .
3. It can be seen from Fig. 3 that the cross-section exhibits an approximate $(W^2)^{2\lambda}$ dependence. The parameter λ slowly increases with increasing energy W and changes from $\lambda \approx 0.23$ at $W = 20$ GeV to $\lambda \approx 0.28$ at $W = 500$ GeV i.e. within the energy range which is relevant for LEP2 and for possible TESLA measurements. These results correspond to the solution of the BFKL equation (16) which contains the non-leading effects generated by the constraint (10). The (predicted) energy dependence of the cross-section $((W^2)^{2\lambda}, \lambda \sim 0.23 - 0.28)$ is marginally steeper than that observed in J/Ψ photo-production [20]. It should however be remembered that the non-leading effects which we have taken into account although being the dominant ones still do not exhaust all next-to-leading QCD corrections to the BFKL kernel [13]. The remaining contributions are expected to reduce the parameter λ but their effect may be expected to be less important than that generated by the constraint (10). The BFKL equation in the leading logarithmic approximation generates a much stronger energy dependence of the cross-section (see Fig. 3).
4. The enhancement of the cross-section is still appreciable after including the dominant non-leading contribution which follows from the constraint (10). Thus while in the Born approximation (i.e. for the elementary two gluon exchange which gives an energy independent cross-section) we get $\sigma_{tot} \sim 1.9 - 2.6$ pb the cross-section calculated from the solution of the BFKL equation with the non-leading effects taken into account can reach the value 4 pb at $W = 20$ GeV and 26 pb for $W = 100$ GeV i.e. for energies which can be accessible at LEP2.

5. Plots shown in Fig. 4 show that the BFKL effects significantly affect the t -dependence of the differential cross-section leading to steeper t -dependence than that generated by the Born term. Possible energy dependence of the diffractive slope is found to be very weak (see Fig. 4). A similar result was also found in the BFKL equation in the leading logarithmic approximation [8].
6. The variation of the parameter s_0 within the range $0.04 \text{ GeV}^2 < s_0 < 0.16 \text{ GeV}^2$ changes normalization of the cross-section by about 30 %. There may still be other sources of normalization uncertainties coming for instance from the use of the nonrelativistic approximation of the impact factor etc. which can increase the normalization error up to 50% or so. The energy dependence of the cross-section is however an unambiguous theoretical prediction.

In our calculations we have assumed dominance of the imaginary part of the production amplitude. The effect of the real part can be taken into account by multiplying the cross-section by the correction factor $1 + tg^2(\pi\lambda/2)$ which for $\lambda \sim 0.25$ can introduce additional enhancement of about 20 %.

It may finally be instructive to confront our results with recent findings concerning the solution of the BFKL equation in the next-to-leading approximation [13, 14, 15]. It has been found that the non leading effects are very important and that the effective intercept λ can become negative in the next-to-leading approximation for relevant values of $\alpha_s > 0.15$. It has been argued that the next-to-leading approximation is not reliable and that one has to perform complete resummation of the non-leading contributions [14, 15]. Let us observe that equation (16) resums to all orders non-leading effects generated by the constraint (10). The difference between exact solution of this equation and its next-to-leading approximation was discussed in ref. [18] for $t = 0$ and for the fixed coupling α_s . It has in particular been found that the exponent λ corresponding to the exact solution stays always positive for arbitrary values of the coupling α_s . The next-to-leading approximation for this exponent differs significantly from the exact solution already for $\alpha_s > 0.2$ and can again become negative. This result confirms the observation [14, 15] that the next-to-leading approximation alone is unreliable and that one has to perform complete resummation of the non-leading effects.

To sum up we have developed the formalism that enabled us to estimate the contribution of the QCD pomeron in the $\gamma\gamma \rightarrow J/\Psi J/\Psi$ diffractive production process. We found that the BFKL effects give a significant enhancement of the cross-section

Figure 4: The differential cross-section of the process $\gamma\gamma \rightarrow J/\Psi J/\Psi$ corresponding to the solution of equation (16) which contains the non-leading effects coming from the kinematical constraint (10) shown for two values of the CM energy W , $W = 50$ GeV (continuous line) and $W = 125$ GeV (dashed line). The short dashed line corresponds to the Born term i.e. to the elementary two gluon exchange mechanism which gives the energy independent cross-section. The parameter s_0 was set equal to 0.10 GeV^2 .

and modify the t -dependence of the Born term. The cross-section exhibits an approximate power law dependence $(W^2)^{2\lambda}$ with $\lambda \sim 0.25$. We based our calculations on the BFKL equation which contained non-leading contributions coming from the constraint imposed upon the available phase space. This constraint is the dominant non-leading effect and it exhausts about 70% of the next-to-leading corrections to the BFKL pomeron intercept. We found that the non-leading contributions generated by constraint (10) significantly affect theoretical expectations based on the BFKL equation in the leading logarithmic approximation. This means that the enhancement of the cross-section although still quite appreciable should be much smaller than that which follows from estimates based on the leading logarithmic approximation [19].
